Prevalence and risk factors of Otitis Media with effusion in school children in Qassim Region of Saudi Arabia

*Qassim University, College of Medicine, Department of Otorhinolaryngology, Qassim, KSA
**Suez Canal University, College of Medicine. Department of Otorhinolaryngology, Ismailia, Egypt.

Abstract:
Objective: To determine the prevalence of otitis media with effusion (OME) among school children in Qassim region of Kingdom of Saudi Arabia and to determine relevant risk factors in affected children.

Methods: Through a cross-sectional study, 1488 children in the age range 6-12 years were randomly selected from 25 primary schools in Qassim region. A questionnaire was used to determine risk factors for OME. Otoscopy and tympanometry were used to diagnose and confirm OME. Pure tone average for children with confirmed OME was measured. Teachers of children were asked to complete a questionnaire evaluating child’s level of school performance.

Results: Prevalence of OME in the study population was 7.5% (112/1488). In univariate analysis, it was strongly associated with age less than 8 years (p<0.0001; OR= 4.23, 95% CI: 2.85-6.29 ), family size more than 4 members in the household((p<0.0001; OR=2.2, 95% CI: 1.47-3.29), recurrent acute otitis media (AOM) (p<0.0001; OR=5.73, 95% CI: 3.47-9.45), and hearing loss symptom (p< 0.0001; OR= 3.39, 95% CI: 1.92-5.99). It is less strongly associated with history of preschool AOM (p= 0.002; OR= 3.15, 95% CI: 1.67-5.97), nasal discharge (p= 0.003; OR= 1.91, 95% CI: 1.24-2.93) and snoring (p=0.03; OR= 1.76, 95% CI: 1.06-2.94). OME was significantly higher in schools located in rural districts (p<0.001, OR= 2.82, 95% CI: 1.86 -4.28). In multivariate regression model, five of these factors were found to be predictors of OME: age less than 8 years (OR= 4.914, 95% CI: 2.677-9.02), family size more than 4 members in the household) (OR= 2.014, 95% CI:1.602-3.877) and recurrent AOM (OR=4.914, 95% CI: 2.677-9.02). Children with OME tend to have poorer school performance compared to normal children (p=0.067). No significant correlation was found between OME and type of feeding during the first two years of life (p=0.62; OR= 0.87, 95% CI: 0.51-1.49), preschool daycare attendance (p=0.17; OR= 0.71, 95% CI: 0.44-1.16), home exposure to cigarette smoke (p=0.4; OR= 1.34, 95% CI:0.68 -2.65), visits to ENT clinic (p=0.13; OR= 0.58, 95% CI:0.29-1.18), and ENT operations (p=0.12; OR= 0.46, 95% CI: 0.17-1.27).

Conclusion: Prevalence of OME in Qassim region reaches 7.5% in school children. Age less than 8 years, family size more than 4 members in the household, mother education lower than secondary school education, living in rural area and recurrent AOM are found to be predictors of OME in Qassim region. In this population of children, otoscopy and tympanometry should be used as screening tools for OME.

Keywords: otitis media effusion, prevalence, risk

Introduction

Nation-wide epidemiological studies for middle ear inflammatory conditions are scarce in Kingdom of Saudi Arabia (KSA). \(^{1, 2}\) Regional studies conducted through local universities help to investigate prevalence of such diseases in different provinces of KSA. These surveys are used by health care planners to properly allocate budget and human resources.

Otitis media with effusion (OME) is a multifactorial disease with infection, possibly biofilm in nature \(^{3, 4}\) and Eustachian tube dysfunction \(^{5}\) are the most widely accepted etiologies. Many risk factors have been associated with this disease: young age \(^{6, 7}\) lack of breast feeding \(^{6, 8, 9}\) low mother education, \(^{9-11}\) low socioeconomic status \(^{6, 10}\) day care attendance \(^{8, 11}\) parental smoking, \(^{6, 11, 12}\) upper respiratory tract infections \(^{6, 9, 11}\) allergy \(^{6, 9, 11, 13, 14}\) and snoring. \(^{6, 9}\)

Although it is a self-limiting condition in the majority of cases, OME may become chronic to the extent that it affects child education and quality of life. Long term effects of this disease on language and academic achievement have been reported, even after the disease had resolved. \(^{15-17}\) Therefore, identification of children at risk of OME is important from medical as well as community perspectives.

In Riyadh prevalence of OME was 13.8 \(^{\%}\)\(^{18}\) and in Abha it was 2.3 \(^{\%}\). \(^{19}\) In Qassim region, no similar studies have been conducted. The purpose of this research is to determine prevalence of OME in school children in Qassim region and to determine demographic, maternal, and child risk factors associated with this disease.

General information about the study area

Qassim is mainly a rural area that reaches 73,000 km. \(^{2}\) Geographically it lies in the middle of Arabian Peninsula and it consists mainly of plateaus and plains with average altitude of 750 m. According to 2010 census, its population reaches 1,215,000. Approximately 21\(^{\%}\) of them are in the age range of 5-14 years. Illiteracy rate is 14\(^{\%}\) in males and 22\(^{\%}\) in females but is steadily decreasing due to extensive educational programs that had been initiated in this province.

Patients and methods

Twenty five schools (12 urban and 13 rural) were randomly selected from the 241 primary public schools in Qassim region. From each school, 65 students in the age range 6-12 years were randomly selected (1625 out of 401 92 students). The study was approved by institutional review boards of Faculty of Medicine-Qassim University and Ministry of Education.

The study was conducted through March 2012 to the end of June 2012. A specific questionnaire was designed in Otorhinolaryngology department in Qassim University. Questionnaire items included child age, gender and grade, number of family members, mother education (illiterate, primary, preparatory, secondary and university), type of feeding in first 2 years of life (bottle, breast or both), exposure to cigarette smoke at home, preschool daycare attendance, preschool AOM, hearing loss as reported by parents, recurrent AOM necessitating antibiotic and analgesic treatment, nasal discharge, snoring, visit to ENT clinic and ENT operations (adenoidectomy, tonsillectomy, myringotomy and ventilation tube insertion). Questionnaires were delivered with consent forms to parents through school administration; the day before examination of children.

Teachers on charge of children were asked to complete a questionnaire evaluating child’s performance. Teachers were asked to classify child’s performance as excellent, very good, good, accepted or poor.

Children with perforated tympanic membrane, ventilation tubes at the time of study, cholesteatoma, craniofacial anomalies or immunodeficiency syndromes were excluded from the study.

A team of an otolaryngologist, a nurse and a social worker visited each school. While collecting the questionnaire, middle ear was assessed with an otoscope and a portable tympanometer. The instrument used was Titan middle ear analyzer (Interacoustics ®, Assens, Denmark) with a probe frequency of 226 Hz and air pressure range of -400 to +100 mm H₂O. Tympanograms were evaluated according to Fielau-Nikolaussen’s \(^{20}\) modification of Jerger’s system: type A: peak between +100 to -100 mm H₂O; type C1: peak between -101 to -200 mm H₂O; type C2: peak between -201 to -300 mm H₂O and type B: no peak detected or pressure could not be measured. Children with obstructive wax that prevents detailed otoscopy had their ear cleaned in the hospital clinic.
before otoscopy and tympanometry. All children with an abnormal otoscopic appearance of OME (retracted tympanic membrane, fluid level or air bubbles) and type B or type C2 tympanograms were reexamined in the hospital clinic using otomicroscopy, repeat tympanometry and pure tone audiometry.

Criteria for diagnosis of OME in this study were set as follows: documented middle ear effusion on microscopy for a minimum of three months, abnormal tympanogram and average air-bone gap of 10 dB. Type C1 tympanogram was not accepted as indicator of OME.

Statistical analysis was performed using SPSS for Windows (Release 17.0 Chicago, SPSS Inc. Chicago, Illinois, USA). Univariate analysis was used to determine association OME with each studied variable. Partial logistic coefficient b, odds ratio and 95% confidence interval were determined for each variable. Risk factors with p-values less than 0.05 were put into multivariate logistic regression model for further investigations. A forward stepwise modeling strategy was applied.

Results:

Out of 1625 candidate children, 1488 were analyzed. Children whose parents refused to fill the questionnaire or to allow clinical examination were excluded from statistical analysis. Wax was obstructive in 245 children (16.4%) and was removed in the hospital clinic.

Results of univariate analysis of risk factors with OME are summarized in Table 1. We found 7.5% of children (112/1488) suffering from persistent OME (>3 months) in at least one ear. OME was bilateral in 32 cases (2.2%) and unilateral in 80 cases (5.3%). Of all children, 7.3% of girls (53/721) and 7.6% of boys (59/767) had OME (Fig. 1) without a statistically significant difference between the two genders (p=0.8 OR = 1.05).

Mean age of children with OME was 8.1±3.8 years and mean age of normal children was 9.4±2.7 years. OME is significantly higher in 6-7 year old children compared to older (8-12 years) children (Table 1) (p<0.0001; OR=4.23, 95% CI=1.55-11.69). Fifty-two percent of children with OME (59/112) were 6-7 year old; 19% (21/112) were 8-9 years old; 20% (22/112) were 10-11 years old and 9% (10/112) were 12 years old (Fig 1).

There was a statistically significant influence of family size on prevalence of OME. It was less common in small families (<4 members) than in bigger families. Ninety-two of children with OME had more than 4 family members in the household compared to 72% of normal children (p<0.001; OR=4.45, 95% CI=2.23-8.88). OME was significantly more in families with mother education less than secondary school education (p<0.0001, OR=2.2; 95% CI=1.47-3.29).

In our study, the type of infant feeding during the first two years of life did not have a significant effect on prevalence of OME in school years. Fifteen percent of those with OME had exclusive bottle feeding compared to 17% of normal children and this was not statistically significant (p=0.62; OR=0.87 95% CI=0.51-1.49).

Regarding daycare attendance in preschool years, 20% of children with OME were sent to daycare centers compared to 25% of normal children and this was not statistically significant (p=0.17; 95% CI =0.44-1.16). Rate of home exposure to cigarette smoke was 7% in normal children and 9% in those with OME. This was again not statistically significant (p=0.4, OR=1.34, 95% CI=0.68-2.65).

Preschool AOM, hearing loss symptom as reported by parents and recurrent AOM were statistically higher in children with OME compared to normal children. Preschool AOM was present in 11.5% of children with OME compared to 4% of normal children (p=0.002; OR=3.15; 95% CI=1.67-5.97). Hearing loss symptom was present in 15% of children with OME compared to 5% of normal children (p<0.0001; OR=3.39; 95% CI=1.92-5.99). Recurrent AOM was present in 23% of children with OME compared to 5% of normal children (p<0.001 OR=5.73; %95 CI=3.47-9.45).

Nasal discharge and snoring were statistically higher in children with OME compared to normal children. Nasal discharge was reported in 30% of children with OME compared to 18% in normal children (p=0.003; OR=1.91 95% CI =1.24-2.93). Snoring was present in 18% of those with OME compared to 11% of normal children (p=0.03; OR=1.76; 95% CI=1.06-2.94).

Eight percent of children with OME and 13% of normal children have visited ear specialist. Rate of ENT operations (adenoidectomy, tonsillectomy and ventilation tubes) was 3.5% in children with OME and 7.5% in children without OME. Difference in these two factors
was not statistically significant ($p=0.13$ and $p=0.12$).

OME was significantly higher in schools located in rural districts than in urban ones ($p<0.001$; OR=2.82; 95% CI= 1.86-4.28) (Table 2). Seventy percent (78/112) of children with OME was living in rural districts compared to 45% (617/1376) of normal children living in these districts.

Results of univariate analysis of factors with statistical significance < 0.05 (Fig. 2) were reviewed using multivariate regression model (Table 3). Only five factors were found significant in this analysis: age less than 8 years (OR=5.052, 95% CI:3.289-7.762), family size more than 4 members in the household (OR= 4.192, 95% CI: 2.033-8.643), rural school district (OR=3.037, 95% CI: 1.933-4.772), mother education less than secondary school education (OR=2.041, 95% CI: 1.602-3.877) and recurrent AOM (OR=4.914, 95% CI: 2.677-9.02).

Evaluation of school performance by responsible teachers revealed that there was statistical trend for children with OME to have poor performance (14/112; 12.5%) compared to normal children (98/1376; 7.1%) although this trend did not reach level of statistical significance ($p=0.067$) (Table 4).

Prevalence and risk factors of Otitis Media with effusion...

Discussion

In our study, overall prevalence of OME was 7.5%. This rate is less than what has been reported by el-Sayed et al., in Riyadh (13.8%)\(^{(18)}\) and more than reported by Abolfotouh et al., in Abha (2.3%).\(^{(19)}\) There is also a considerable variation in the prevalence of OME in worldwide studies. It was 16% in Turkey,\(^{(16)}\) 6.8% in Italy\(^{(17)}\), 9.5% in Netherlands\(^{(21)}\) and 6.5% in Greece.\(^{(22)}\) It seems that OME is affected by the type of population studied, the geographical area and its prevailing climate.

In our study, maximum prevalence was in the first two school grades (Fig. 1) and it tends to
decrease in later grades. In multivariate regression model, there was a statistically significant correlation between OME and ageless than 8 years (p<0.0001; OR= 5.052, 95% CI: 3.289-7.762). Our results go with the opinion that age is one of the most important risk factors for OME. (6, 7, 23, 24) Ziehlhuis et al., used the age specific prevalence of OME and concluded that there are two peaks for the disease: one around 2 years and the other around 5 years While OME generally decreases after the age of five, it continues to be seen in a significant proportion of school-age children. (25)

In our study, we found no significant association between genders in prevalence of OME (OR=1.05 95% CI=0.71-1.54). Our results are similar to study done Kiris et al., and by Engel et al. In these studies, neither male nor female gender was identified as strong predictor of OME in school children. (6, 24) Other studies showed higher prevalence among girls (9) or among boys. (21, 26) According to Tos et al., gender difference in otitis media represents mainly the influence of cultural factors. (27)

In our study, children with OME had larger number of family members in household than normal children (p= <0.0001). From multivariate regression model, we found that family size of more than 4 members is one of the strongest predictors of OME (OR= 4.192, 95% CI: 2.033-8.643). Our results are similar to those reported by Sassen et al., (23) They found that presence of older siblings is an important factor in occurrence of OME. Probability of disease increases with each additional brother or sister. In Australia, Jacoby P. et al., found higher risk of carriage of bacteria causing otitis media in aboriginal children compared to non-aboriginal children. They highlighted the need to reduce the crowding in Aboriginal households. (28) Gultekin et al., (11) and Martines et al., (9) however, found no difference in the number of household between children with and without OME.

In our study, low mother education was found to be a risk factor for OME. In multivariate regression model, mother education less than secondary school education was found to be a predictor of OME (p< 0.001; OR=2.041, 95% CI:1.602-3.877). Similarly Gultekin et al., reported higher prevalence of OME in families with less parental education. (11) Daly et al., also found that lower levels of maternal education were associated with poorer knowledge regarding otitis media. (30)

In our study, children who were never breast fed during the first two years of life did not have higher prevalence of OME than those who had exclusive breast or mixed type of feeding (p=0.62; OR=0.87 95%=0.51-1.49). Our results are similar to those done by Glutekin et al. and Tong et al. (11,31) A protective effect of breast feeding against AOM in preschool children was reported by Abrahams et al. (32) However, Sassen et al., found that 12 months after breast-feeding was discontinued, the risk was virtually the same as if the child had never been breast-fed. (33)

In our study, one quarter of children without OME went to day care centers in preschool years compared to 20% of those with OME. Although we did not find a significant relationship between OME and daycare attendance (p=0.4, OR=0.71 95% CI:0.44-1.16), maintaining good hygiene in daycare facilities and their supervision by health and education officials are essential in order to reduce rates of upper respiratory tract infection in young children attending these facilities. (11, 34, 35)

One of the most studied risk factors of OME is exposure to smoking at home. (36) Some studies, using serum, salivary and urinary cotinine as indicator of passive smoke exposure, were able to demonstrate significant relationship to OME. (37-39) In our study, rate of exposure to passive smoking was unexpectedly low (7%). We could not establish a statistically significant relation between exposure to passive smoking and development of OME. (p=0.4, OR=1.34 95% CI:0.68-2.65). Higher rates of smoking were previously reported in Saudi families but it seems that parents are becoming increasingly aware of hazards of passive smoking on their children. (40)

In our study, 11.5% of children with OME had preschool AOM compared to 4% of normal children and this was statistically significant (p=0.002). In univariate analysis, children with OME were three times more likely to have preschool AOM (OR= 3.15 95% CI=1.67-5.97). Kiris et al report some of children continue to have middle ear problem secondary to Eustachian tube dysfunction and large adenoid, particularly in first or second grade. (6)

From univariate analysis, hearing loss symptom was significantly higher in children
with OME (p=0.0001 OR=3.39, 95%CI= 1.92-5.99). However, in multivariate analysis, it was not significant. In general, sensitivity of parent-suspected hearing impairment seems to be quiet low (15% in our study). Only 8% of children with OME visited ENT clinic and 3.5 % of them had ENT operations (adenoidectomy, tonsillectomy and ventilation tubes). Health education of parents helps to increase their awareness of this silent disease and this has been recommended by Lo et al.\(^{41}\)

In our study, 23% of children with OME had recurrent AOM compared to 7% in normal children, (p<0.0001). In the multivariate regression model, we found recurrent AOM to be a strong predictor of OME in this age\((OR=4.914, 95\%\ CI: 2.677-9.02)\). Martines et al., and Alho et al., similarly found that children with history of recurrent AOM are more likely to have OME.\(^{9,42}\)

Nasal discharge, when it is persistent or recurrent, affects the Eustachian tube and middle ear in children.\(^{23,43}\) Snoring whether due to rhinitis or large adenoids is more common in children with chronic ear problems.\(^{9,16}\) In our study, thirty percent of children with OME had nasal discharge compared to 18 % of normal children \((p=0.003, \ OR=1.91\ 95\%\ CI=1.24-2.93)\). Snoring was reported in 18% of children with OME compared to 11% of normal children \((p= 0.03, \ OR=1.76;\ 95\%\ CI= 1.06-2.94)\). Relation of these two symptoms as risk factors associated with OME has been reported by Kiris et al.\(^{6}\)

In our study, OME was more prevalent in rural district schools (Table 2) than in urban district schools. This can be explained by low socioeconomic status and less access to healthcare facilities in multivariate regression model, rural school district is one of the predictors of OME \((p<0.001, \ OR=3.037, 95\%\ CI: 1.933-4.772)\). Although, Martines et al., found no effect of socioeconomic class on disease prevalence,\(^{9}\) others ascertain that it has a significant effect.\(^{44,45}\)

Regarding school performance, we found only a statistical trend for students with OME to have poorer school performance than normal students \((p=0.067)\) (Table 3). Similarly, Kiris et al.,\(^{6}\) found that children with OME had low success levels compared to normal children but the difference in their study was slight (10.7 vs. 6.8%). Conductive hearing loss especially when bilateral \((32/112\ children\ in\ our\ study)\) impairs child attention during classes. Using actual student scores in statistical analysis, instead of ranks or grades would have increased statistical power.

Limitations in our study is that we relied on self-reports from the parents. This may be a source of recall bias. ‘Yes or no’ choices in most of questionnaire items, used for its brevity, might not have allowed parents to give their exact response.

**Conclusions**

Prevalence of OME in Qassim region reaches 7.5% in school children. Age less than 8 years, family size more than 4 members in the household, mother education less than secondary school education, living in rural area and recurrent AOM are found to be predictors of OME in Qassim region. In this population of children, otoscopy and tympanometry should be used as screening tools for OME.
